Anders Møller & Michael I. Schwartzbach
Computer Science, Aarhus University

Interprocedural analysis

- Analyzing the body of a single function:
 - *intra*procedural analysis
- Analyzing the whole program with function calls:
 - *inter*procedural analysis
- For now, we consider TIP without function pointers and indirect calls
- A naive approach:
 - analyze each function in isolation
 - be maximally pessimistic about results of function calls
 - rarely sufficient precision...

Add WeChat powcoder

CFG for whole programs

The idea:

- construct a CFG for each function
- then glue them together to reflect function calls and returns

<https://powcoder.com>

We need to take care of:

Add WeChat powcoder

- parameter passing
- return values
- values of local variables across calls
(including recursive functions, so not enough to assume unique variable names)

A simplifying assumption

- Assume that all function calls are of the form

$$X = f(E_1, \dots, E_n);$$

<https://powcoder.com>

- This can always be obtained by normalization

Interprocedural CFGs (1/3)

Split each original call node

$X = f(E_1, \dots, E_n)$

<https://powcoder.com>

into two nodes:

Add WeChat powcoder

$\square = f(E_1, \dots, E_n)$

← the “call node”

$X = \square$

← the “after-call node”

a special edge that
connects the call node
with its after-call node

Interprocedural CFGs (2/3)

Change each return node

return E

<https://powcoder.com>

into an assignment:

Add WeChat powcoder

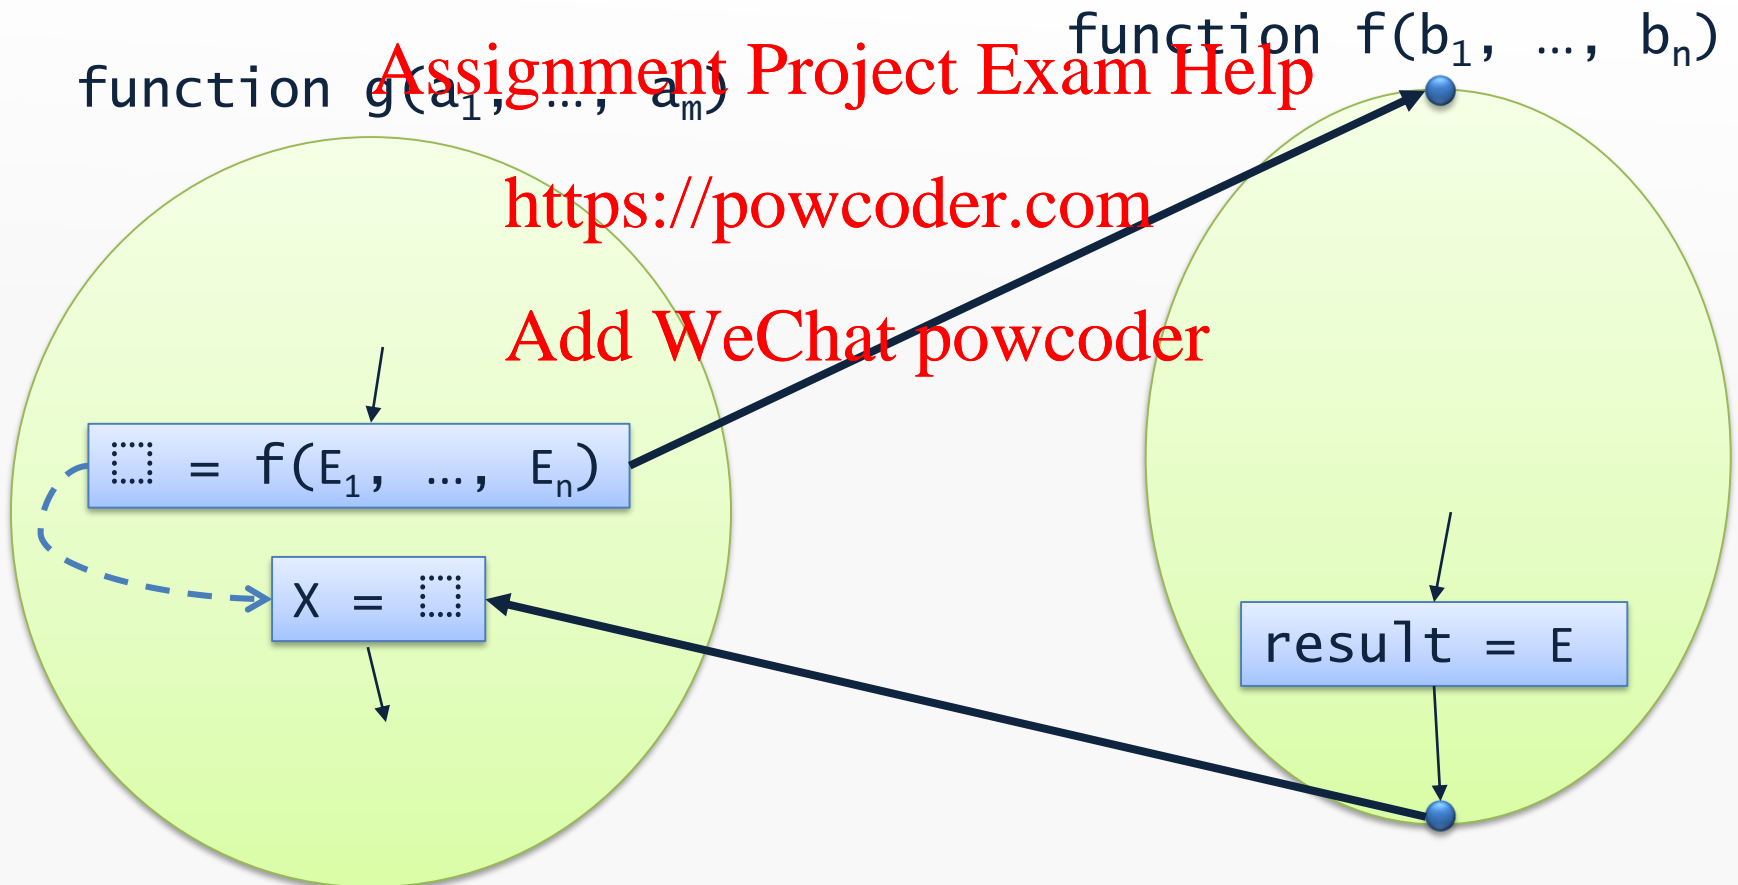

result = E

(where `result` is a fresh variable)

Interprocedural CFGs (3/3)

Add call edges and return edges:

Constraints

- For call/entry nodes:
 - be careful to model evaluation of *all* the actual parameters before binding them to the formal parameter names (otherwise, it may fail for recursive functions)
- For after-call/exit nodes:
 - like an assignment: `X = result`
 - but also restore local variables from before the call using the call \rightarrow after-call edge
- The details depend on the specific analysis...

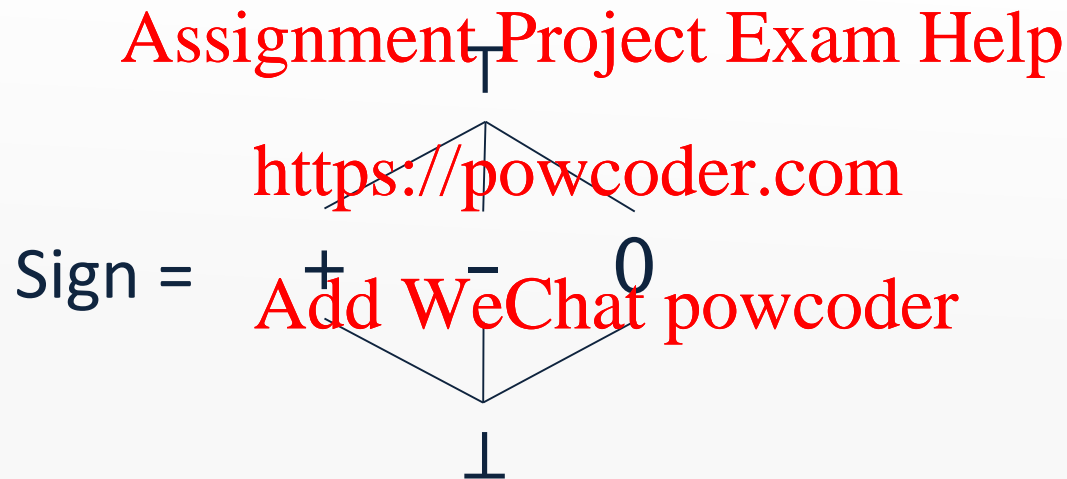

Assignment Project Exam Help

<https://powcoder.com>

Add WeChat powcoder

Example: interprocedural sign analysis

- Recall the intraprocedural sign analysis...
- Lattice for abstract values:

- Lattice for abstract states:
 $Vars \rightarrow Sign$

Example: interprocedural sign analysis

- Constraint for entry node v of function $f(b_1, \dots, b_n)$:

$$\llbracket v \rrbracket = \bigsqcup_{w \in \text{pred}(v)} \perp [b_1 \rightarrow \text{eval}(\llbracket w \rrbracket, E_1^w), \dots, b_n \rightarrow \text{eval}(\llbracket w \rrbracket, E_n^w)]$$

Assignment Project Exam Help

where E_i^w is i th argument at w

<https://powcoder.com>

- Constraint for after-call node v labeled $X = \square$,
with call node v'

$$\llbracket v \rrbracket = \llbracket v' \rrbracket [X \rightarrow \llbracket w \rrbracket(\text{result})]$$

where $w \in \text{pred}(v)$

(Recall: no global variables, no heap,
and no higher-order functions)

Alternative formulations

$$1) \llbracket v \rrbracket = t_v(\bigsqcup_{w \in \text{pred}(v)} \llbracket w \rrbracket)$$

Assignment Project Exam Help

$$2) \forall w \in \text{succ}(v): t_v(\llbracket v \rrbracket) \sqsubseteq \llbracket w \rrbracket$$

- recall "solving inequations"
- may require fewer join operations if there are many CFG edges
- more suitable for *interprocedural* flow

The worklist algorithm (original version)

```
x1 = ⊥; ... xn = ⊥
```

```
W = {v1, ..., vn}
```

```
while (W ≠ ∅) {
```

```
    vi = W.removeNext()
```

```
    y = fi(x1, ..., xn)
```

```
    if (y ≠ xi) {
```

```
        for (vj ∈ dep(vi)) {
```

```
            W.add(vj)
```

```
        }
```

```
        xi = y
```

```
    }
```

```
}
```

Assignment Project Exam Help

<https://powcoder.com>

Add WeChat powcoder

The worklist algorithm (alternative version)

```

 $x_1 = \perp; \dots x_n = \perp$ 
 $W = \{v_1, \dots, v_p\}$ 
while ( $W \neq \emptyset$ ) {
     $v_i = W.removeNext()$ 
     $y = t_i(x_i)$ 
    for ( $v_j \in dep(v_i)$ ) {
        propagate( $y, v_j$ )
    }
}

```

```

propagate( $y, v_j$ ) {
     $z = x_j \sqcup y$ 
    if ( $z \neq x_j$ ) {
         $x_j = z$ 
         $W.add(v_j)$ 
    }
}

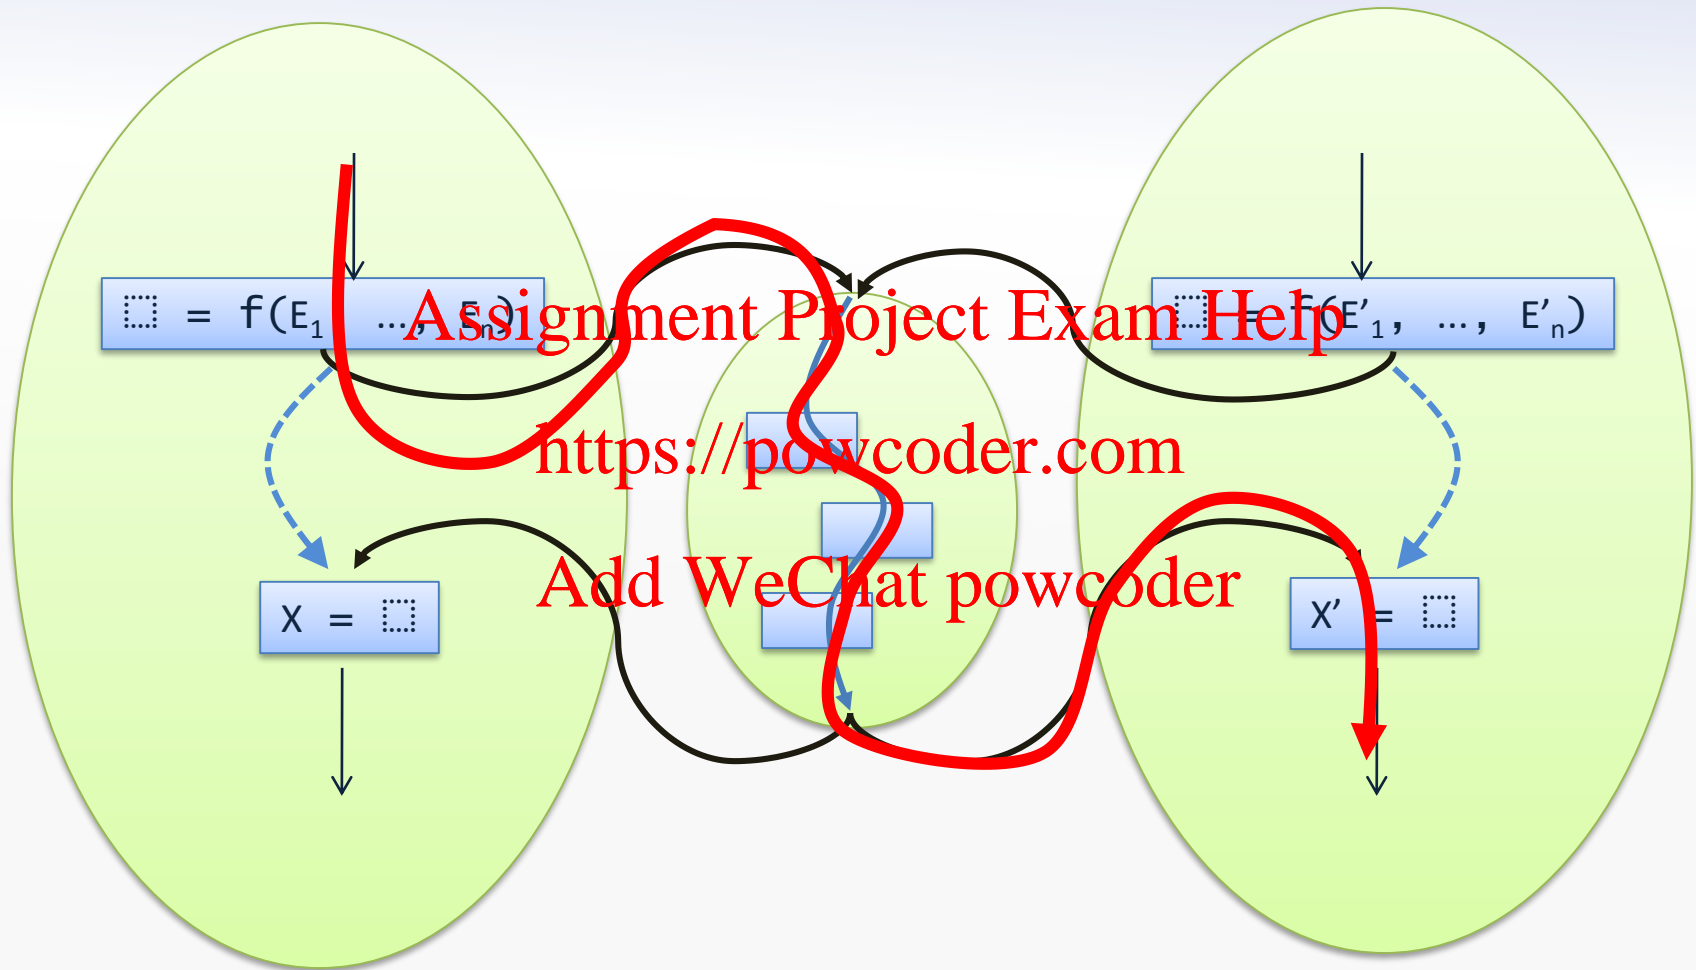

```

Implementation: `worklistFixpointPropagationSolver`

Agenda

- **Interprocedural analysis**
 - **Context-sensitive interprocedural analysis**
- <https://powcoder.com>
Add WeChat powcoder

Interprocedurally invalid paths

Example

What is the sign of the return value of g?

```
f(z) {  
    return z*42;  
}
```

Assignment Project Exam Help

<https://powcoder.com>

Add WeChat powcoder

```
g() {  
    var x,y;  
    x = f(0);  
    y = f(87);  
    return x + y;  
}
```

Our current analysis says “T”

Function cloning (alternatively, function inlining)

- Clone functions such that each function has only one callee

Assignment Project Exam Help

- Can avoid interprocedurally invalid paths 😊
<https://powcoder.com>
- For high nesting depths, gives exponential blow-up 😐
Add WeChat powcoder
- Doesn't work on (mutually) recursive functions 😞
- Use heuristics to determine when to apply (trade-off between CFG size and precision)

Example, with cloning

What is the sign of the return value of g?

```
f1(z1) {  
    return z1*42;  
}
```

Assignment Project Exam Help

```
f2(z2) {  
    return z2*42;  
}
```

<https://powcoder.com>
Add WeChat powcoder

```
g() {  
    var x,y;  
    x = f1(0);  
    y = f2(87);  
    return x + y;  
}
```

Context sensitive analysis

- Function cloning provides a kind of context sensitivity (also called polyvariant analysis)

- Instead of physically copying the function CFGs, do it *logically*

Assignment Project Exam Help

- Replace the lattice for abstract states, States, by

<https://powcoder.com>

Contexts \rightarrow lift(States)

Add WeChat powcoder

where Contexts is a set of ***call contexts***

- the contexts are abstractions of the state at function entry
 - Contexts must be finite to ensure finite height of the lattice
 - the bottom element of lift(States) represents “unreachable” contexts
- Different strategies for choosing the set Contexts...

One-level cloning

- Let c_1, \dots, c_n be the call nodes in the program
- Define $\text{Contexts} = \{c_1, \dots, c_n\} \cup \{\varepsilon\}$
 - each call node now defines its own “call context”
(using ε to represent the call context at the main function)
 - the context is then like the return address of the top-most stack frame in the call stack
- Same effect as one-level cloning, but without actually copying the function CFGs
- Usually straightforward to generalize the constraints for a context insensitive analysis to this lattice
- (Example: context-sensitive sign analysis – later...)

Assignment Project Exam Help

<https://powcoder.com>

Add WeChat powcoder

The call string approach

- Let c_1, \dots, c_n be the call nodes in the program
- Define Contexts as the set of strings over $\{c_1, \dots, c_n\}$ of length $\leq k$
 - such a string represents the top-most k call locations on the call stack
 - the empty string ϵ again represents the call context at the main function
- For $k=1$ this amounts to one-level cloning

Implementation: CallStringSignAnalysis

Example:

interprocedural sign analysis with call strings ($k=1$)

Lattice for abstract states: $\text{Contexts} \rightarrow \text{lift}(\text{Vars} \rightarrow \text{Sign})$
where $\text{Contexts} = \{\varepsilon, c_1, c_2\}$

```
f(z) {
```

```
  var t1, t2;
```

```
  t1 = z*6;
```

```
  t2 = t1*7;
```

```
  return t2;
```

```
}
```

```
...
```

```
x = f(0); // c1
```

```
y = f(87); // c2
```

```
...
```

Assignment Project Exam Help

<https://powcoder.com>

Add WeChat powcoder

$[\varepsilon \mapsto \text{unreachable},$

$c_1 \mapsto \perp[z \mapsto 0, t_1 \mapsto 0, t_2 \mapsto 0],$

$c_2 \mapsto \perp[z \mapsto +, t_1 \mapsto +, t_2 \mapsto +]]$

What is an example program
that requires $k=2$
to avoid loss of precision?

Context sensitivity with call strings

function entry nodes, for $k=1$

Constraint for entry node v of function $f(b_1, \dots, b_n)$:
(if not 'main')

Assignment Project Exam Help

$$\llbracket v \rrbracket(c) = \bigsqcup_{\substack{w \in \text{pred}(v) \wedge \\ c = w \wedge \\ c' \in \text{Contexts}}} s_w^{c'}$$

$w \in \text{pred}(v) \wedge$

$c = w \wedge$

$c' \in \text{Contexts}$

$$s_w^{c'} = \begin{cases} \text{unreachable} & \text{if } \llbracket w \rrbracket(c') = \text{unreachable} \\ \perp[b_1 \rightarrow eval(\llbracket w \rrbracket(c'), E_1^w), \dots, b_n \rightarrow eval(\llbracket w \rrbracket(c'), E_n^w)] & \text{otherwise} \end{cases}$$

Context sensitivity with call strings after-call nodes, for k=1

Constraint for after-call node v labeled $X = \square$,
with call node v' and exit node w expected

$$\llbracket v \rrbracket(c) = \begin{cases} \text{unreachable} & \text{if } \llbracket v' \rrbracket(c) = \text{unreachable} \vee \llbracket w \rrbracket(v') = \text{unreachable} \\ \llbracket v' \rrbracket(c)[X \rightarrow \llbracket w \rrbracket(v')(result)] & \text{otherwise} \end{cases}$$

The functional approach

- The call string approach considers *control flow*
 - but why distinguish between two different call sites if their abstract states are the same?
- The functional approach instead considers *data*
- In the most general form, choose
Contexts = States
(requires States to be finite)
- Each element of the lattice $\text{States} \rightarrow \text{lift}(\text{States})$ is now a map m that provides an element $m(x)$ from States (or “unreachable”) for each possible x where x describes the state at function entry

Example:

interprocedural sign analysis with the functional approach

Lattice for abstract states: $\text{Contexts} \rightarrow \text{lift}(\text{Vars} \rightarrow \text{Sign})$

where $\text{Contexts} = \text{Vars} \rightarrow \text{Sign}$

```
f(z) {  
  var t1, t2;  
  t1 = z*6;  
  t2 = t1*7;  
  return t2;  
}
```

...

```
x = f(0);
```

```
y = f(87);
```

...

Assignment Project Exam Help

<https://powcoder.com>

Add WeChat powcoder

$$\begin{aligned} \perp[z \mapsto 0] &\mapsto \perp[z \mapsto 0, t1 \mapsto 0, t2 \mapsto 0], \\ \perp[z \mapsto +] &\mapsto \perp[z \mapsto +, t1 \mapsto +, t2 \mapsto +], \\ \text{all other contexts} &\mapsto \text{unreachable} \end{aligned}$$

The functional approach

- The lattice element for a function exit node is thus a ***function summary*** that maps abstract function input to abstract function output
- This can be exploited at call nodes!
- When entering a function with abstract state x :
 - consider the function summary s for that function
 - if $s(x)$ already has been computed, use that to model the entire function body, then proceed directly to the after-call node
- Avoids the problem with interprocedurally invalid paths!
- ...but may be expensive if States is large

Implementation: FunctionalSignAnalysis

Context sensitivity with the functional approach

function entry nodes

Constraint for entry node v of function $f(b_1, \dots, b_n)$:
(if not 'main')

$$\llbracket v \rrbracket(c) = \bigsqcup_{\substack{w \in \text{pred}(v), \\ c = s_w^{c'} \wedge \\ c' \in \text{Contexts}}} s_w^c$$

<https://powcoder.com>

Add WeChat powcoder

where $s_w^{c'}$ is defined as before

Context sensitivity with the functional approach

after-call nodes

Constraint for after-call node v labeled $X = \square$,
with call node v' and exit node $w \in \text{pred}(v)$:

<https://powcoder.com>

$$\llbracket v \rrbracket(c) = \begin{cases} \text{unreachable} & \text{if } \llbracket v' \rrbracket(c) = \text{unreachable} \vee \llbracket w \rrbracket(s_{v'}^c) = \text{unreachable} \\ \llbracket v' \rrbracket(c)[X \rightarrow \llbracket w \rrbracket(s_{v'}^c)(\text{result})] & \text{otherwise} \end{cases}$$
